

• For IMF:

$$i) \int_{M_A}^{M_B} \xi(M) dM = N \quad \left(\begin{array}{l} \text{number of stars} \\ \text{with mass } M_A \\ \text{to } M_B \end{array} \right)$$

→ We can find the Mass in this region

$$M_{A \rightarrow B} = \int_{M_A}^{M_B} M \cdot \xi(M) dM$$

[total mass between M_A and M_B]

* So the average Mass (for PS 2 opt. (a))

$$\langle M \rangle = \int_{M_A}^{M_B} M (M \cdot \xi(M)) dM$$

• In lecture we used the value for the Number of stars instead of mass which for this problem was wrong
